

ABSTRACT OF THE DISCLOSURE

An organic electroluminescence display. The display comprises a transparent electrode, a metal electrode and a
5 organic thin layer which is disposed between the pair of electrodes and which includes a light emitting layer. The metal electrode has a reflection scattering property. Since the metal electrode has a reflection scattering property, the ambient light is reflected in various directions so that the reflected light
10 returns and is incident on the color filter. In this way, within the incident light due to reflection scattering on any of the filter regions that has a different color from that of light already transmitted through the filter regions, light with different wavelength from that of the incident light is
15 attenuated. Accordingly, the reflection of the ambient light is further attenuated.
